Strategies and tactics for ironic subversion

Tony Veale

Ironic descriptions subvert the norms of descriptive language. Norms have highly salient exemplars – shared stereotypes – on which speakers can draw to create a vivid description, but ironic speakers instead construct their own counter-examples, often identifying exceptional cases where the standard inferences do not hold. One can thus hone one's facility for irony by studying the ironic descriptions of others. Indeed, specific tactics for implementing a particular strategy for irony can be acquired by observing how others use words to subvert our own expectations. In this chapter we provide the computational foundations for uniting these ideas into a single analytical framework. These foundations comprise: a nuanced knowledge representation of stereotypes and their most salient properties, acquired from a large-scale analysis of web similes; a set of non-literal query operators for retrieving phrases with ironic potential from a large corpus of linguistic readymades (such as the Google n-grams); a corpus of annotated similes, harvested from the web; tools for detecting irony in similes harvested from the web; and automatic tools for deriving specific tactics for irony from these attested cases.

1. Readymade forms, and the soul of a new cliché

Samuel Goldwyn, the co-founder of MGM studios, famously summed up Hollywood's attitude to creativity with the line “Let’s have some new clichés”. On the face of it, this seems like just another one of Goldwyn’s many memorable mis-statements (like “include me out!”): after all, it’s hard to think of clichés as new, or as something that can be invented on demand. Yet, on closer analysis, one can find real insight in Goldwyn’s remark. Clichés are considered anathema to the creative process because they represent everything that is conventional and jaded about the status quo. However, clichés become tired through overwork, and are overworked precisely because they prove themselves so useful in so many different contexts. Few writers set out to create a new cliché, but most would like their efforts to become as much a part of the fabric of our linguistic culture as the most tenacious of clichés.

All rights reserved
One productive form of a new cliché is the humorously pithy comparison, as in “as durable as a chocolate teapot” or “as useful as a screen door on a submarine”. Speakers recognize memorable comparisons when they hear them, and re-use them as eagerly as one retells a favorite joke. The most frequently reused comparisons can, in this way, acquire the clichéd status of a proverbial simile. When the folklorist Archer Taylor collected his corpus of proverbial similes in 1954, he observed not just a wide variety of humorous comparisons in American speech, but a wide variety of humorous forms for the same descriptive qualities, such as “durable” and “useful”. Speakers are clearly drawn to popular comparisons of proven value, but are equally fond of coining their own, in the hope that their witty new descriptions are widely reused by others in turn. This constant churn of re-invention keeps our language fresh, and ensures that ironic comparisons retain their ability to challenge and to entertain, even as others – such as “crazy like a fox!” and “as clear as mud!” – acquire an idiomatic status which makes them effortlessly understood.

Stereotypes anchor a comparison in the realm of the familiar, where judgments about representativeness are made quickly and intuitively by cognitive processes that Kahneman (2011) dubs System 1. Conversely, similes help to perpetuate stereotypes by packaging them into such conveniently re-usable linguistic forms. However, ironic similes subvert the workings of System 1, and force us to engage a set of deliberative, analytic and non-intuitive processes that Kahneman dubs System 2. Whereas straight similes use stereotypes as exemplars of a given quality, ironic similes highlight the unexpected lack of this quality by instead using a withering counter-example, perhaps constructed from stereotypes that one intuitively associates with very different (and even antonymous) qualities. Humorously ironic comparisons often construct this counter-example by subverting the normal form of a stereotype. Thus, while we expect a vault to be the very model of a secure location, we might describe a weak and unsafe container as being “as secure as a chocolate vault”. The stereotypes “chocolate” and “vault” are combined here to produce a complex concept with internal incongruities (secure and strong versus brittle and soft) that lead to emergent qualities (such as not secure at all). Novel combinations such as “chocolate vault” require insights that can only come from System 2, to override those that are produced by System 1.

Nonetheless, after encountering a variety of sardonic utterances that are anchored in a construct such as “chocolate X”, we might infer a general rule: If X is a stereotype of strength or solidity or durability or some related quality, then an X made of chocolate will have none of these qualities. Repeated exposure to the “chocolate X” pattern will help us acquire a meta-cliché that we can use, in turn,
to generate novel instances of our own, such as “chocolate tank” and “chocolate castle”. Of course, we cannot simply stick the prefix “chocolate” in front of an arbitrary stereotype and hope for the best; rather we need a means of identifying meaningful combinations.

An approach to linguistic creativity called *Creative Information Retrieval* (Veale 2011) offers such a means. This chapter describes how CIR allows us to harvest readymade phrases from a web corpus such as the Google n-grams (Brants and Franz 2006)), and enables us to identify the most likely qualities of the concepts denoted by those phrases. Section 2 shows how the stereotypical knowledge exploited by CIR is acquired from web-harvested similes, and considers the signs, and the likelihood, that a web-harvested simile is in fact ironic. Building on these foundations, Section 3 presents a set of powerful CIR query operators, which can be used to retrieve similes, metaphors, analogies and other pithy descriptions from corpora. In Sections 4 and 5, this knowledge is applied to a corpus of similes that has been annotated for irony, to automatically learn a set of patterns, or metaclichés, than can then be used to generate novel descriptions that mischievously set up, and then ironically subvert, the meanings that the conventions of the simile form has primed an audience to expect.

2. **Stereotypes, similes and irony**

Similes – even ironic similes – exploit mutual knowledge of stereotypical norms to communicate their meanings, even if these norms are ultimately subverted. As such, similes are also an ideal source of stereotypical knowledge for a *tabula rasa* agent such as a computer, for as Dickens notes in *A Christmas Carol*, “the wisdom of our ancestors is in the simile”. There is, however, an important caveat: such agents are liable to make the worst mistakes possible if they misread a speaker’s intention to be ironic.

Veale and Hao (2007a) explored the use of similes as a source of stereotypical norms, and harvested tens of thousands of simile bodies (of the form “as X as a Y”) from the web. Lacking an automatic procedure for filtering straight similes from ironic similes, Veale and Hao (2007a) filtered their simile-set manually, to obtain a collection of over 12,000 unique straight simile bodies (such as “as hot as an oven”) and almost 3000 unique ironic simile bodies (such as “as subtle as a sledgehammer”). Veale and Hao (2007b) then used the straight similes as a source of stereotypical norms (e.g. ovens are hot, jungles are humid, snow is soft) in a system for comprehending and generating metaphors.
The unused ironic similes were later used as a test-set for an irony detection algorithm in Veale and Hao (2010). A simple question was posed of each simile in the combined set (straight + ironic): can a simile “as X as Y” be plausibly recast in a form that is highly likely to be non-ironic, or can it more plausibly be recast in a form that is highly likely to be ironic? For the idealized non-ironic form, the pattern “X Zs such as Xs” was chosen, since irony is very infrequently observed in this construction. Thus, the simile “as hot as a sauna” is recast as “hot Zs such as saunas”. For the idealized ironic form, the pattern “about as X as Y” was chosen, since “about” has been hypothesized to be a subtle marker of irony (Moon 2008). Thus, the simile “as muscular as a paper-clip” is recast as “about as muscular as a paper-clip”. To test the plausibility of each recasting, simple web frequency for each form was calculated using the search engine Google. Though Veale and Hao (2010) describe a number of ancillary heuristics in their methodology, this simple recasting is the backbone of their approach, which achieves promising results overall: 87% of ironic similes are recognized with .63 precision, while 89% of straight similes are recognized with .97 precision. The F-score for classification of ironic similes is .73, for straight similes it is .93, and for irony/straight classification overall it is .88.

Veale (2012) used the “about” construction to harvest a collection of irony-rich similes, and extended the form of the search to accept complex similes in which the vehicle is a multiword phrase (such as “a wet rag” or “a chocolate teapot”). This collection of 20,299 web similes was then hand-annotated for irony, so that it could be used as a gold-set for future irony studies. To appreciate the wittily creative nature of many of these similes, consider the following list of descriptions that serve as vehicles in web similes of the form “about as useful as …”. Any vehicle which underpins a web simile that is subsequently annotated as ironic is prefixed with a *.

\begin{itemize}
\item about as useful as …
\item *a chocolate teapot
\item *tits on a bull
\item *a chocolate fireguard
\item *a cow’s fifth teat
\item *buying one shoe
\item *a fish on a bicycle
\item *a football bat
\item *a clock
\item *tits on burnt bacon
\item *crystal balls
\item *knickers on a kipper
\item *a one legged man at an arse kicking contest
\item *a chocolate tea kettle
\item *a screen door on a submarine
\item *a steam engine in getting to the moon
\item *a coalman on a maglev monorail
\item *looking at tea leaves
\item *an appendix
\item *an infected scrotum
\item *teats on a bull
\item a microscope
\item *a third nipple
\end{itemize}
*biodegradable house paint  *an ashray in a motorcycle
*a 10 ton rock in a canoe  *a useless thing
*teats on a boar  *side pockets on a cow
*polka dots to a polar bear  *a one armed man on a building site
*a chocolate fireplace  *a dog chasing a parked car
*a dead house plant  *an old vacuum tube
*a raincoat in the desert  *teaching aerobics to the homeless
*a fridge at the North Pole  *scuba diving with an umbrella
*tapeworms  Google Scholar
*a hat full of busted assholes  *a blunt pocket knife
*a case of jock itch  *a penis on a priest
*watching paint dry  *an asshole hole on my elbow
*a solar telescope  *a fart in a spacecraft
*Ouija boards  *truth at a political convention
*handles on a banana  *an old pair of underwear
*tits on a nun  *a wet cowpie in the summer sun
*bloodletting  *a van full of 8 track cartridges
*a tinfoil hat  *mammary glands on a chicken
*toilet paper for a fish  *a knock on the head
*square wheels  *training wheels for tricycles
*a bag full of farts  *a knife in a gun fight
*a hole in the head  *a chocolate saucepan
*an inflatable dart board  *a condom machine in the Vatican
*a snow cone in Siberia  *a broken pencil
*an inflatable dart board  *a knob on the head
*a cluch on a walrus  *air conditioning on a motorbike
*a pork chop in a synagogue  *a cautery on a wooden leg
*a foam hammer  *bucket brigades to fight fires in skyscrapers
*a warm bucket of spit  *a pocketknife in a laser tag arena
*an umbrella in a volcano  *a windshield wiper on a goat’s ass

The preponderance of * in the above list shows that “about” similes for the ground “useful” on the web are almost always ironic. Yet “about” does not so much signal irony as it does a sardonic attitude. Consider these additional “about” web similes for the opposite of “useful”, namely “useless”:

about as useless as …
a screen door on a submarine  tits on a bull
JPEGs to Helen Keller  the Windows firewall
tits on a boar hog  a sore thumb
*teats on a boar hog  udders on a bull
a football bat  a one legged man in an ass kicking contest
*a hat full of busted assholes  a cat flap in an elephant house
a chocolate teapot
a hole in the head
an appendix
a milk bucket under a bull
a solar powered lightbulb
a flat tire
a pair of tits on a boar
a gun with no bullets
an ashtray on a motorcycle
a damp squid
an umbrella in the desert
tits on a male dog
mammary glands on a boar
a male nipple
an asshole on my elbow
the prick on the pope
a chocolate fireguard
an old wart
a 3-dollar bill
an inflamed appendix
tits on a nun
a bra on a horse
condoms at a monastery
tits on a frog
a bikini store in Antarctica
a chocolate spacesuit
wheels on a fish

inviting triangles to a circle convention
a marzipan dildo
the underside of a desk in a nuclear explosion
a cocktail umbrella in a thunderstorm
a three legged cat
an inverted penis
knees on a fish
an old shoe
a toothpick in a canoe
a pinky toe
a fart in a spacesuit
soggy toilet paper
a three legged dog
riding cross country on a midget unicycle
a condom in a convent
a cell phone tied to a wall
a liberal in a gunfight
a canoe in the middle of the desert
a fish out of water
a brick
a toenail in a donkey factory
a pool of runny turd at a pottery contest
an extra navel
a fish with a bicycle
glass hammers
a broken chair
a sneaker full of shit

Vehicles that are common to both the “useful” and “useless” web similes are highlighted in bold, while the vehicles of ironic similes are again marked with an *. However, no vehicles at all are marked with * in the “useless” similes above, for while most of these examples are wittily sardonic, none is actually ironic. That is, no “about as useless as” simile in our web corpus employs an example of something useful to ironically subvert our expectation of an exemplar of uselessness. Irony is a device for conveying a critical perspective, and one rarely criticizes something for being useful. The “about” marker alone does not signal irony but a playful imprecision. When “about” is used with a negative ground such as “useless”, the result is a playfully negative description. But when “about” is used with a positive ground such as “useful”, the result is also likely to be a playfully negative description. Whether or not the “about” marker introduces an ironic or straight simile hinges on the affective qualities of the ground property.
That being said, our web corpus lends further support to the role of “about” and other markers of imprecision (such as “not exactly X” and “almost as X as”) in signaling ironic intent in the right affective circumstances, since 76% of the newly harvested similes (such as “about as modern as a top-hatted chimneysweep”) are marked as ironic, and the vast majority of these employ a positive ground to impart a negative, critical meaning (see Veale [2012] for a full analysis). Just 14% of these 20,299 “about” simile types use a vehicle with a single content-word, and a mere 3% (i.e., 676 types) are also found in the original harvesting process of Veale and Hao (2007a). So the “about” marker not only signals a speaker’s intention to be playful and perhaps ironic, it also signals a speaker’s intention to be witty and perhaps creative. When computers aim to be ironic in their use of novel descriptions, the “about” construction can thus help ensure that their efforts are more readily received as intentionally ironic.

2.1 Modeling stereotypical behaviors

As noted by Dickens, the collective knowledge provided by stereotype-anchored similes yields a consensus model of common-sense norms. This conventional knowledge, which echoes our conventional expectations of a given concept, is precisely the kind of knowledge that is humorously subverted by irony. However, the simile pattern “as X as Y” – first used by Veale and Hao to harvest stereotypical associations from the web – is limited to the retrieval of adjectival descriptions, such as the fact that ovens are hot, bows are curved and arrows are straight. It cannot harvest stereotypical behaviors, such as the fact that babies drool, politicians lie, and dogs bark.

To rectify this limitation and to simultaneously enlarge the stereotypical model underpinning the current approach to irony, we use a bottom-up, evidence-driven approach to identify both stereotypical properties and behaviors for a given topic. We first harvest all 3-word phrases from the Google 3-grams that match the pattern <DET PROPERTY NOUN>. Here PROPERTY can match either an adjectival case in WordNet (Fellbaum 1998) or an inflected verb that denotes a behavior, such as swaggering or armored. For adjectival cases, we generate the as-simile “as ADJ as a NOUN”, while for verbal behaviors we generate the like-simile “BEHAVIOR like a NOUN”. We then use the resulting simile as a web query to see how many times the simile occurs on the web. That is, as-similes are generated for adjectival properties and like-similes are generated for verbal behaviors, so e.g. the 3-gram “a reckless cowboy” yields the query “as reckless as a cowboy” and the 3-gram “a swaggering cowboy” yields “swaggering like a cowboy”. 
We next consider only the queries that return a non-zero result set; these correspond to stereotypical associations that have been attested by usage on the web. Nonetheless, this set still contains a great deal of noise, and we find many underspecified behaviors such as “walking like a drunk” or “talking like a baby”. We could use statistical techniques here to separate the most discriminating behaviors (e.g., “staggering like a drunk” and “babbling like a baby”) from the least informative (e.g., “walking like a sailor”). Yet, since this task only needs to be done once to create a precise and highly reusable lexico-conceptual resource, we do it manually to achieve the best results.

It takes a matter of weeks to perform manual filtering, but the stereotype model that results from this effort is significantly larger than that produced by Veale and Hao (2007a). Consider the term baby: the new resource suggests 163 associations as being stereotypical of babies:

{delicate, squalling, weeping, baptized, adopted, startled, attentive, blessed, teeny, rocked, adorable, whining, bundled, toothless, placid, expected, rescued, treasured, new, sleepy, indulged, slumbering, weaned, pure, supple, helpless, small, sleeping, animated, vulnerable, wailing, cradled, kicking, soft, rested, bellowing, blameless, grinning, screaming, orphaned, mute, cherished, reliant, thriving, loveable, guileless, sniveling, inexperience, harmless, dribbling, unthreatening, nursed, angelic, bawling, beaming, tame, naked, spoiled, scared, weak, squirming, blubbing, contented, smiling, wiggling, mewling, blubbing, sniffing, overtired, dimpled, loving, dear, tired, powerless, bewildered, peaceful, distressed, naive, wee, soiled, sucking, fussy, gurgling, vaccinated, heartwarming, pouting, constipated, drooling, quiet, wiggly, lovable, bare, weaning, suckling, cute, bald, whimpering, tender, pampered, incontinent, fleshy, charming, dependent, artless, fussing, flabby, babbling, warm, giddy, crawling, snoozing, hairless, cuddled, sweet, sobbing, squalling, wrapped, tiny, cooing, swaddled, laughing, toddling, fragile, innocent, moaning, gentle, terrified, precious, cranky, giggling, confused, pink, cuddly, fat, ignorant, snoring, young, howling, screeching, shrieking, trusting, shivering, napping, resting, frightened, fresh, loved, demanding, chubby, adored, appealing, happy, relaxed, bumbling, wriggly, rocking, wriggling, conceived, clean, content, smooth, crying, submissive}  

In all, the new resource contains over 75,000 unique noun-to-property associations. These associations describe a total of 9,479 different stereotypes, ascribing to each a selection of 7,898 different properties and behaviors. This compares very favorably with the 12,000+ associations in Veale and Hao's (2007a) original resource.

3. Creative information retrieval

Ironic utterances can be viewed as congruous statements in incongruous contexts. As Wilson and Sperber (1992) put it in their echoic-mention theory of irony, an ironic utterance echoes one that would plausibly be made in a very different context, thus drawing an audience’s attention to a failure of expectations in the current context. One can ironically echo an utterance that is explicitly associated with another context (an explicit echo) or one can allude to a general expectation arising from another context (an implicit echo). Fludernik (2007) generalizes this notion of an implicit echo to include any pointed allusion to accepted beliefs, received wisdom, or stereotypical norms. In any case, to process irony a computer needs the ability to retrieve either the appropriate utterance or the appropriate norm. Veale (2011) describes a platform for the retrieval of creative language that can be used to achieve each of these ends.

Creativity often arises from a process of appropriation, in which something is wrenched from its normative context of use and given new meaning in a new setting. In this vein, Duchamp popularized the notion of an artistic ready-made when his Fountain – a signed urinal – was presented with some controversy at a Dada exhibition in 1917. We normally think of readymades as physical objects whose artistic merit derives wholly from their selection by an artist, but language is also rich in linguistic readymades. Just think of how many movies, songs, novels, poems, etc. allusively borrow utterances and phrases from each other. For example, the movie The Usual Suspects takes its name from a famous quote from the movie Casablanca, while the novel All The King’s Men takes its title from a famous nursery rhyme; this title has, in turn, inspired the title of Woodward and Bernstein’s book All The President’s Men.

The well-formed phrases that one can extract from the Google database of n-grams can be viewed as a vast collection of linguistic readymades, insofar as each is a phrase that is wrenched from its original context of use on the web. To find the right readymade for a given task, one needs a set of retrieval tools that go beyond the normal range of query operators that are employed in standard IR. Veale (2011) describes a set of non-literal query operators that allow a user to search for n-grams on the basis of metaphorical similarity rather than literal string similarity. These operators are denoted @, ? and ^ and defined thus:

@ is the stereotype operator, where @noun will match any stereotypical property of noun and @adj matches any noun denoting a concept that has the stereotypical property adj. For example, @razor will thus match the words “sharp”, “straight”, “clean” and “smooth”, while @sharp will match any of the words “razor”, “knife”, “sword”, and so on.
is the neighborhood operator, where ?noun will match any other noun that is frequently clustered with noun, and ?adj will match any other adjective that is frequently used with adj in a complex description. The neighborhood for nouns is determined by gathering matches for the pattern “Xs and Ys” (a coordination of bare plurals) in the Google n-grams (such as “angels and demons”, “doctors and nurses”, “cups and saucers”, etc.), while the neighborhood for adjectives is determined by gathering matches for the pattern “as X and Y as” (a multi-property simile) on the web. For example, ?disaster will match any of the words “tragedy”, “catastrophe”, “calamity”, “misfortune”, “hardship”, “plague”, “famine” and so on, while ?tragic will match any of the words “sad”, “shocking”, “terrible”, “unfortunate”, “ridiculous” and so on. All matches for ?noun are ranked by the WordNet similarity of each match to noun, while matches for ?adj are ranked by the co-occurrence frequency of each match with adj on the web.

^ is the category operator, where ^class will match any member of the pre-defined category class. Users can give names to their own ad-hoc categories, or designate names for the results of previous retrievals (for instance, a user might populate the category ^sharptool with words that match the CIR query @sharp & ^tool). The ^ operator can also be used to refer to WordNet categories; e.g., ^person matches any noun denoting a kind of person in WordNet.

To these three operators we add a fourth:

- is the antonym operator, where -P will match any antonym of the adjective P. Antonyms are derived from the lexical resource WordNet. Thus, for example, -soft matches the word “hard”, and -strong matches the word “weak”.

Importantly, these non-literal operators can be used in complex combinations. For instance, ?@adj will match any noun in the neighborhood of a noun / concept that exhibits the stereotypical property adj, while @-adj will match any noun / concept that is a stereotypical holder of any property denoted by an antonym of adj. Likewise, @?adj will match any noun / concept with a stereotypical property that is like adj, while @@noun will match any other noun / concept that shares at least one stereotypical property with noun.

Veale (2011) describes how non-literal operators, when used to augment an IR system for retrieving Google n-grams, can provide a generic foundation for retrieval-oriented linguistic creativity. For instance, CIR can be used to turn the readymade phrases of the Google n-grams into vehicles for creative comparison. For a topic X and a property P, straight similes of the form “X is as P as S” are easily generated by retrieving values for S ∈ (@P ∩ ??X). Likewise, the query “?P @P” will retrieve corpus-attested elaborations of stereotypes in @P to suggest similes of the form “X is as P as (?P @P)”. The simile “as cold as a fish” can thus be elaborated to yield “as cold as a wet fish”, “as cold as a dead haddock”, “as cold
as a wet January”, “as cold as a frozen corpse”, and “as cold as a heartless robot”. Complex queries can retrieve more elaborate vehicles for creative similes, so “@P @P” (which retrieves “robot fish” and “snow storm” for cold) and “?P @P @P” (e.g. “creamy chocolate mousse” for rich) each retrieve n-grams that blend two different but overlapping stereotypes.

By using the antonym operator -, ironic similes can also be generated for the P-ness of a topic X using the pattern “X is as P as (@-P ⊓ ??X)”. In effect, (@-P ⊓ ??X) finds counter-examples of P-ness that are comparable to X, rather than the kind of stereotypical examples that we expect in the normative, non-ironic use of as-similes. However, adjectives can be ambiguous, and -P may not always yield an appropriate antonym for the intended sense of P.

4. Strategies for ironic subversion

The use of antonym-based counter-examples is just one strategy that is available to the ironic speaker. We can express this strategy S_{antonym} in CIR terms as follows:

\[ S_{antonym}(P) \leftarrow {?P @-P} \]

In other words, a set of ironic expressions for a property P can be found by retrieving all 2-gram phrases where the first word is an adjective that reinforces the idea of -P (any antonym of P) and the second word is a noun denoting a concept for which any element of -P is stereotypical. Thus, for example, the phrase “soggy pillow” is retrieved for the property hard, since soft & hard are conventional antonyms and stored as such in WordNet.

Since we so often seek to impress with irony, our goal is not merely to communicate an implicit negation, but to communicate an implicit negation in the most imaginative, memorable and quotable words we can muster. A vivid juxtaposition of ideas can help us to achieve this goal. We can thus use the following variant of the S_{antonym} strategy:

\[ S_{combo}(P) \leftarrow {-P} @-P \]

For example, since a wall is typically hard, and a good basis for ironic descriptions of softness, the phrases “brick wall”, “stone wall”, “steel wall”, “titanium wall”, “oak wall”, “granite wall” etc. are retrieved by S_{combo}(soft). Likewise, phrases like “marshmallow bunny” and “jelly baby” – which can seem decidedly odd, and thus fresh and imaginative when considered out of their original context – are retrieved as ironic descriptions of hardness. In this way, strategies like S_{combo} embody Fishelov’s (1992) view of poetic similes, by providing more elaborate and more vivid mental images than a single stereotype alone could do. A computer that uses a database
of readymade phrases to suggest possible word/idea combinations for creative descriptions is thus tapping into the collective imagination of many different speakers at once.

We shall use the term “strategy” to denote a high-level approach to generating ironic descriptions, where each such approach is represented as a CIR query for retrieving matching phrases from a corpus such as the Google n-grams. For instance, we can define another strategy $S_{\text{group}}$ that is defined via the following CIR query:

$$S_{\text{group}}(P) \leftarrow (\neg \text{group} \land @P) \text{“of” } @-P$$

The CIR query for $S_{\text{group}}$ matches any 3-gram phrase in which: the first word denotes both a group (like family or army) and a concept for which the given property $P$ is stereotypical; the second word is the string literal “of”; and the third word is a noun that denotes a concept for which the antonym of the given property $P$ is stereotypical. Under normal circumstances, any word matching $(\neg \text{group} \land @P)$ would serve as an excellent example of $P$-ness, denoting a mass of $P$ stereotypes in a coherent grouping. However, $S_{\text{group}}$ finds phrases that subvert this stereotypical group, by populating the group with counter-examples of $P$-ness. Thus, “army of dreamers”, “army of civilians” and “army of irregulars” are all retrieved from the Google 3-grams as ironic vehicles for the property disciplined, while the 3-grams “army of cowards”, “army of babies”, “army of ants”, “army of cripples”, “army of kittens”, “army of girls” and “army of worms” are retrieved for strong. Notice the way in which $S_{\text{group}}$ creates descriptions that suggest $P$-ness right up to the last word, whereupon a final ironic reversal of meaning is delivered. $S_{\text{group}}$ can thus be viewed as a more sophisticated ironic version of the adolescent strategy for generating sarcasm, where “Not!” is placed at the end of an otherwise affirmative utterance.

To use the language of Attardo and Raskin’s General Theory of Verbal Humor, or GTVH (1991), each strategy is effectively a logical mechanism that causes an incongruous combination of ideas to be juxtaposed, and to be subsequently resolved as an attempt at irony. In $S_{\text{antonym}}$ and $S_{\text{group}}$ the incongruity derives from lexical knowledge of antonyms and the properties they denote. For example, consider the following strategy, named $S_{\text{material}}$:

$$S_{\text{material}}(P) \leftarrow (\neg \text{material} \land @-P) \land P$$

The category $\neg \text{material}$ is populated with elements of the WordNet category $\neg \text{substance}$ for which 3-gram matches can be found for the CIR query “made of $\neg \text{substance}$”, such as “chocolate”, “concrete”, “steel”, etc. Thus, though brick is a stereotypically hard object, $S_{\text{material}}(\text{hard})$ is populated with the 2-gram phrases “silk brick”, “snow brick” and “water brick”. To provide a garden-path effect, each vehicle can be re-formulated so that the ironic kicker is found at the end of the phrase, as in “a brick made of silk”, “a brick made of snow” and “a brick made of water”. © 2013. John Benjamins Publishing Company
All rights reserved
As shown in $S_{\text{antonym}}$, $S_{\text{combo}}$, $S_{\text{group}}$, and $S_{\text{material}}$, each CIR query acts as a high-level rule in which the key elements are matched non-literally against a large corpus of phrasal n-grams. But, as in all high-level rules, each rule may give rise to unexpected, low-level exceptions. Words in unexpected combinations can have specific nuances that we cannot predict from high-level rules alone, and specific combinations may not give rise to the desired ironic effect. To address this problem, high-level strategies — such as those we have considered above — should be implemented via lower-level tactics that specifically employ words that have a proven record of generating ironic effects.

5. Tactics for ironic subversion

An important goal of this work is the creation of software with a human-like capacity for ironic description. A software instantiation of even a basic model of linguistic irony can offer both scientific and engineering insights into the model: for one, it provides a concrete test of the unambiguous, algorithmic specificity of the model; and it allows us to construct practical dialogue systems that interact more naturally, more forcefully and more engagingly with humans because they show a clearer understanding of the goals and strategies of human communication. For just as humans learn from the language of others, a computer can similarly learn from the examples that it encounters, provided it is capable of deconstructing these examples (e.g. Winston 1982). More specifically, a computer can learn specific tactics for each ironic strategy by considering specific instances of ironic descriptions. So, given an ability to detect irony in figurative comparisons, a computer can observe which ironic comparisons instantiate which strategies, and thus learn word-specific tactics for each of these strategies from new examples as they arise. The Veale/Hao corpus of annotated about-as-similes serves as a large set of initial observations from which to work (Veale 2012; Hao and Veale 2010).

Consider this ironic simile from the Veale/Hao corpus, describing the level of password protection in MS Word: “about as secure as a cardboard bank vault”. Both bank and vault are stereotypically associated with the ground property secure, so “bank vault” is a compound term with the same stereotypical association. The original simile thus exhibits the following general pattern: “about as secure as a cardboard @secure”. Since the simile is annotated as ironic, its ironic effect must emerge from its specific use of the word “cardboard”. That is, cardboard must possess some quality that subverts the secureness of an otherwise very secure container. This case appears to be a specific use of the $S_{\text{material}}$ strategy, yet insecure is not a stereotypical property of cardboard, so there is no semantic incongruity between cardboard and secure (as there is between concrete and soft, say, or marshmallow and hard). In such a context, when used to describe a container that should
be secure, *cardboard* prompts the emergent inference that it is not secure at all. This specific use of words suggests this tactic for irony:

\[ T_{\text{cardboard}}(\text{secure}) \leftarrow \text{"cardboard" } \text{@secure} \]

Tactics, labeled with a T, are more specific than strategies (labeled with an S). Note how the tactic above contains a literal content-word (*cardboard*), and pertains to a specific property (*secure*) rather than to a generic property $P$. Tactics implement a high-level strategy, but are bound to specific words and derive from attested examples of irony. It is the strategy, when applied to the specific example, that allows the computer to understand the workings of the example and to generate the corresponding tactic. So when used to retrieve phrases from the Google 2-grams, the tactic $T_{\text{cardboard}}(\text{secure})$ above suggests these other ironic descriptions of a secure location: “cardboard fortress”, “cardboard bank”, “cardboard jail” and “cardboard prison”.

The opposition found in ironic descriptions tends to be pragmatic rather than semantic, and relies on experiential knowledge of the world. This kind of opposition is unlikely to be found in lexico-semantic resources like WordNet. For instance, consider this simile which is marked as ironic:

“about as *sharp* as a rubber carving knife”

Since carving knives are stereotypically sharp, the *rubber* modifier must be subverting this quality to produce an ironic counter-example. Our knowledge of the world tells us that rubber objects are unlikely to be very sharp, and even those that look pointy are probably too flexible to do any real harm. This example provides the following tactic:

\[ T_{\text{rubber}}(\text{sharp}) \leftarrow \text{"rubber" } \text{@sharp} \]

Phrases retrieved using CIR for this tactic include: “rubber sword”, “rubber shark”, “rubber pencil”, “rubber arrow”, “rubber dart”, “rubber tooth” and “rubber dagger”. Similar modifiers like “plastic” can subvert multiple properties across different stereotypes. Consider the examples “about as *sharp* as a plastic knife” and “about as *pretty* as a plastic flower” which yield the following two tactics:

\[ T_{\text{plastic}}(\text{sharp}) \leftarrow \text{"plastic" } \text{@sharp} \]
\[ T_{\text{plastic}}(\text{pretty}) \leftarrow \text{"plastic" } \text{@pretty} \]

Even in cases such as these, where there is no obvious semantic incongruity between the features of the words in the description and the property that is ironically conveyed, we should expect a stereotypical model of the world to help a computer appreciate the logic of an ironic pairing. Consider another attested simile that is marked as ironic:

All rights reserved
“about as *threatening* as a wet puppy”

As humans who have experience of real puppies, we know them to be unthreatening and an unlikely source of fear. Yet we cannot realistically expect our models of the world to enumerate all of the properties that our stereotypes do *not* typically possess. To a computer, there must be some property that puppies *do* typically possess that makes them unthreatening, a property that is even more salient when they are *wet*. Since *threatening* and *harmless* are antonyms, the qualities of stereotypical puppies that make them unthreatening are those that make them more *harmless*, such as being *soft* and *gentle*. Both *soft* and *gentle* are prominent members of *harmless*, and our web-derived knowledge-base contains 16 stereotypes that are both *soft* and *harmless*, and 10 that are both *soft* and *gentle*. The following two tactics can thus be inferred.

\[
\begin{align*}
T_{\text{wet+soft}}(\text{threatening}) & \leftarrow \text{“wet”} @\text{soft} \
T_{\text{wet+gentle}}(\text{threatening}) & \leftarrow \text{“wet”} @\text{gentle}
\end{align*}
\]

T_{\text{wet+soft}} (threatening) and T_{\text{wet+gentle}} (threatening) are specific tactics that implement the generic strategy S_{proxy}. Numbers in parentheses indicate the matching scores of *soft* for *harmless* and of *gentle* for *harmless* respectively. Since these tactics rely on unsafe inferences (e.g. that soft things are mostly harmless), the scores provide confidence levels for the corresponding tactics. Phrases retrieved for T_{\text{wet+soft}} (threatening) include “wet diaper”, “wet poodle” and “wet blanket”, while CIR retrieves phrases such as “wet breeze” and “wet sheep” for T_{\text{wet+gentle}} (threatening). In this example, *wet* and *threatening* are not antonyms, yet *wet* helps to undermine the potential of the ironic counter-example to pose a threat. Other similes annotated as ironic, such as “about as threatening as a sleeping poodle” and “about as threatening as a dead hamster”, allow a computer to infer that *sleeping* and *dead* can be just as effective in subverting the property *threatening*. The tactics that result from these examples retrieve other ironic vehicles, such as “sleeping lamb” and “dead goldfish”.

Some properties that are commonly subverted by irony are so generic that they are only noticed when they are absent. Consider the property *useful*: all man-made objects are designed to be useful, but their usefulness derives from a wide-range of other, context-specific properties. When we complete the ironic simile “about as *useful* as …” we often create mental images of dysfunctional objects that can no longer serve their original intended purposes. Consider this attested example from the web: “about as *useful* as a foam hammer”. Foam is typically neither useful nor useless. However, hammers need to be *hard* to function well, and foam is stereotypically *soft*, so an opposition between *hard* and *soft* can be detected here. This gives rise to this tactic:
Hardness does not imply usefulness any more than softness implies uselessness, but the attested example of a foam hammer gives us a reusable pattern from which to build new ironic examples. Phrases retrieved from Google 2-grams for this tactic include “foam wall”, “foam knife” and the enigmatic “foam tombstone”. We detect a similar opposition in the following example from the web: “about as useful as a rubber crutch”. Crutches are stereotypically rigid, while rubber is typically flexible. This opposition of rigid and flexible yields the following tactic for generating uselessly un-rigid objects:

\[ T_{\text{rubber}+\text{rigid}}(\text{useful}) \leftarrow \text{“rubber” @rigid} \]

Phrases retrieved by this tactic include “rubber sword” (which is also an ironic counter-example for sharpness), “rubber tripod”, “rubber clamp” and “rubber poker”.

6. Conclusion: A middleware foundation for linguistic creativity

The research reported in this chapter makes a two-fold contribution to the computational study of irony, and of linguistic creativity more generally. To enable computers to learn from the frequent use of irony by human speakers on the web, just as human speakers learn from each other, the problem of ironic description generation has been divided into a two-tier system of general strategies (which, like the logical mechanisms of the GTVH, do not appeal to specific lexemes) and of specific tactics (which instantiate higher-level strategies using words with specific properties). The separation of strategies from tactics proves to be a useful basis for finding and studying real uses of irony; moreover, as researchers identify more strategies for ironic description, we can use these computational models to identify the most productive tactics for those strategies. Yet the mechanisms of CIR – Creative Information Retrieval – can be used for more than the matching of ironic strategies and tactics. CIR offers a powerful means of exploiting a language’s vast trove of linguistic readymades for diverse forms of language creativity, such as the crafting of novel similes and metaphors. Veale (2012) presents a variety of generative applications that use CIR as a middleware layer for linguistic creativity.

While creative irony subverts the norms of conventional communication to playfully dash an audience’s expectations, ironic descriptions obey their own higher-level norms for constructing counter-examples. We have used the term strategy throughout to refer to these high-level norms of ironic description, and have outlined a variety of strategies – such as \( S_{\text{group}} \) and \( S_{\text{proxy}} \) – in this chapter. Strategies are generic: they show how one can construct a counter-example for a
property $P$ from stereotypes for $P$ or from antonyms of $P$, or from stereotypes of (the neighbors of) antonyms of $P$. But for irony to be humorously clever, it must do more than state an obvious negation: it must create the circumstances for this negation to emerge from an unlikely pairing of ideas. Emergent properties are of course difficult to predict, and they emerge from specific contexts, not from generic rules. For instance, bank vaults are stereotypically secure, while a vault made of cardboard is anything but secure. However, a cardboard bank vault is more an illustrative thought experiment than a real object: no sensible person would ever construct such a container to function as a real bank vault, yet the workings of language and thought allow us to at least contemplate the possibility of such an exceptional object (Gendler 2000). The result may be pragmatically silly on one level – the level of real functionality – but it is semantically valid, and has pragmatic value as a conveyer of meaning if not as a container of money. It takes imagination to create these humorous follies, but as with jokes, there are reusable patterns that one can exploit.

The CIR framework that allows us to codify these patterns as strategies and tactics has been evaluated in Veale (2011, 2012). The complementary layers of manually-defined strategies and automatically-extracted tactics have now been implemented upon this foundation, to yield the various tactical patterns and their retrieved instances we have described here. Thus far, yields are low but promising: of the 15,554 about-as-similes that are annotated as ironic in the Veale/Hao data set, just over 10% yield a reusable tactic that can be applied – via creative information retrieval – to an n-gram database to retrieve further ironic suggestions. In total, 1,694 tactics are acquired from the annotated similes, such as the following:

$$T_{\text{unweaned} \oplus \text{gentle}}(\text{savage}) \leftarrow \text{“unweaned” } @\text{gentle}$$

This tactic, derived from the attested ironic simile “about as savage as an unweaned pup”, serves a dual purpose: it offers an explanatory interpretation of the irony in similes of this kind, by understanding the vehicle as an exemplar of youthful gentleness rather than of animal savagery; and it allows a computer to exploit this understanding to compose novel similes of its own, albeit with a similar logic. Nonetheless, the search for readymade phrases that can satisfy a particular tactic can yield some truly unexpected word pairings, as when “foam tombstone” is retrieved as an ironic exemplar of hard, or “rubber tripod” for useful.

The next steps in this work include an evaluation of the outputs of the system by real users who demand real irony. We shall also need to improve the tactical yield of the system, to extract more tactics from our existing corpus of annotated similes (and thereby identify more of the logical mechanisms/strategies that shape these similes), to acquire more examples of creatively ironic similes from the web,
and to extend the reach of the tactics that are successfully extracted. These are related goals. For instance, given that strong, secure and durable are related properties that are mutually reinforcing (e.g. strong containers tend to be secure, secure containers tend to be durable and strong, and so on), it should be possible then to generalize a tactic like $T_{\text{cardboard}}$ (secure) to create related tactics like $T_{\text{cardboard}}$ (strong). Indeed, once a modifier like “cardboard” is seen to have tactical value in ironic similes for the property secure, a system can generate targeted web queries using other words in ?secure, such as:

“about as strong as a cardboard”
“about as durable as a cardboard”
“about as reliable as a cardboard”
“about as trustworthy as a cardboard”

Since the inspiration for these patterns is an attested ironic simile, we can expect that most matches for these patterns on the web will be ironic also. For instance, we find the following matches for “about as reliable as a cardboard” via the Google API: “cardboard boat”, “cardboard bridge”, “cardboard shelter”, “cardboard oven glove”, “cardboard umbrella”, “cardboard raft” and “cardboard lifebelt”. By using its understanding of known examples to perform a targeted exploration of the web in this fashion, a CIR-driven computational system can acquire, and actively learn from, a constantly growing corpus of ironic examples. In this way, a computer can develop and steadily hone its own ironic sensibility over time, while allowing us as scholars of humor to better appreciate the nature of this humorously subversive phenomenon.
